EXPERIMENT 13

Enterprise limitations case study

Aim

Analyze where the low code design may fall short for a large multi-branch service network and propose an architecture.

Procedure

1. Hypothetical scenario (assumptions, not measured limits): 25 branches, 500,000 historical requests, mobile technician apps, central identity, parts transfers between branches, peak walk-in load.
2. Turn it into acceptance targets: response time, downtime, data residency, audit retention, concurrent bay/technician allocation, offline behaviour, recovery time.
3. Map each requirement to a native capability, extension, or unresolved constraint; check current quotas, API limits and licensing.
4. Design proof-of-concept tests: concurrent bay allocation, peak dashboard load, delayed sync, identity revocation.
5. Compare all-Creator, hybrid and custom with weighted criteria; write a recommendation and exit strategy.

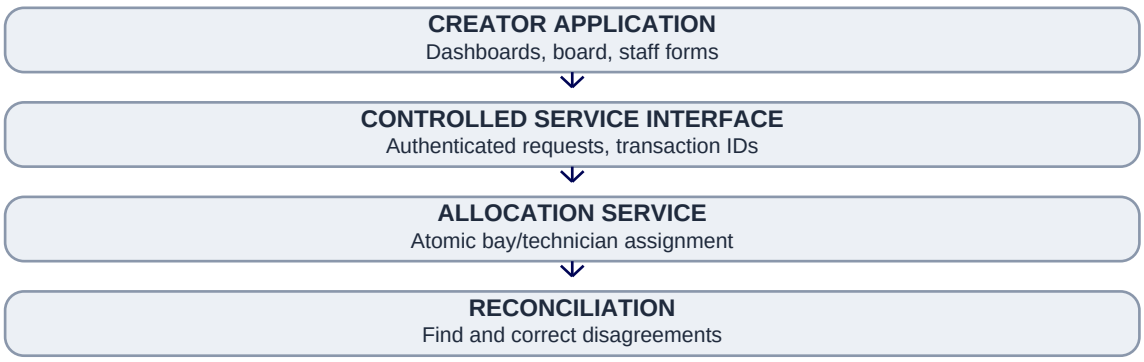
Implementation and verification

Risk	Consequence	Mitigation to evaluate
Concurrent bay allocation	Two vehicles assigned one bay	Single authoritative allocation service
Offline mobile use	Stale status	Online-only final status or reconciliation rules
Large reporting load	Slow pages, quota hit	Pagination, archival, measured queries
Cross-service updates	Creator and external state differ	Idempotency keys, retries, reconciliation
Vendor dependency	Cost / portability	Export drills, contract review

Evidence and testing

E13: acceptance targets, risk register, recommendation with stated assumptions.

Process diagram



Generated explanatory diagram. It is not a screenshot of an executed workflow.

Result

Expected result and verification criteria. A defensible recommendation with explicit assumptions; no unsupported claim that low code cannot scale or that it meets every enterprise need.
